Go through mathematical notation of the PRML book.

Introduction

- **Pattern Recognition**
is concerned with the automatic discovery of regularities in data using algorithms and to take actions such as classifying the data into different categories.
- **Example:** recognizing handwritten digits

Introduction

- Each digit corresponds to a 28×28-pixel image.
- The image is represented by a vector \mathbf{x} comprising 784 real numbers.
- The goal is to build a machine that will take such a vector \mathbf{x} as input and produce the identity of the digit 0, . . . , 9 as the output.

Introduction

To build a model to recognize handwritten digits:

- We need a dataset (training set) to make the machine learn from it.
- The dataset consists of N images of digits. Each image has a label to indicate the target value.
- The target value of the image is what we want to predict.
- The set of target values of the N digits are called **target vector t** .
- Each image of the data set is called an **instance (example) x** .

Introduction

- **Exercise:**

If a dataset is a set of images, what are considered as features and what is considered as a target?

| Introduction |
| Polynomial Curve Fitting |
| Bayesian Probabilities |
| Bayesian Curve Fitting |

Polynomial Curve Fitting

- We start with a regression example, given a real-valued input x , we want to predict its target value t .
- We will create an artificial dataset:
 - The number of samples is 10 data points.
 - The feature vector is $\mathbf{x} = (x_1, x_2, \dots, x_n)^T$ is a value in range $[0, 1]$
 - The target vector is $\mathbf{t} = (t_1, t_2, \dots, t_n)^T$ derived from the function $\sin(2\pi x)$ with added noise.
- Our goal is to **learn** from the given training data to discover the underlying function of $\sin(2\pi x)$.
 - If we discover the underlying function, we can predict the target value \hat{t} given a new value \hat{x} .

Polynomial Curve Fitting

Figure 1.2 Plot of a training data set of $N = 10$ points, shown as blue circles, each comprising an observation of the input variable x along with the corresponding target variable t . The green curve shows the function $\sin(2\pi x)$ used to generate the data. Our goal is to predict the value of t for some new value of x , without knowledge of the green curve.

Polynomial Curve Fitting

- We will implement a **linear regression** model.
- The linear regression model is defined as:

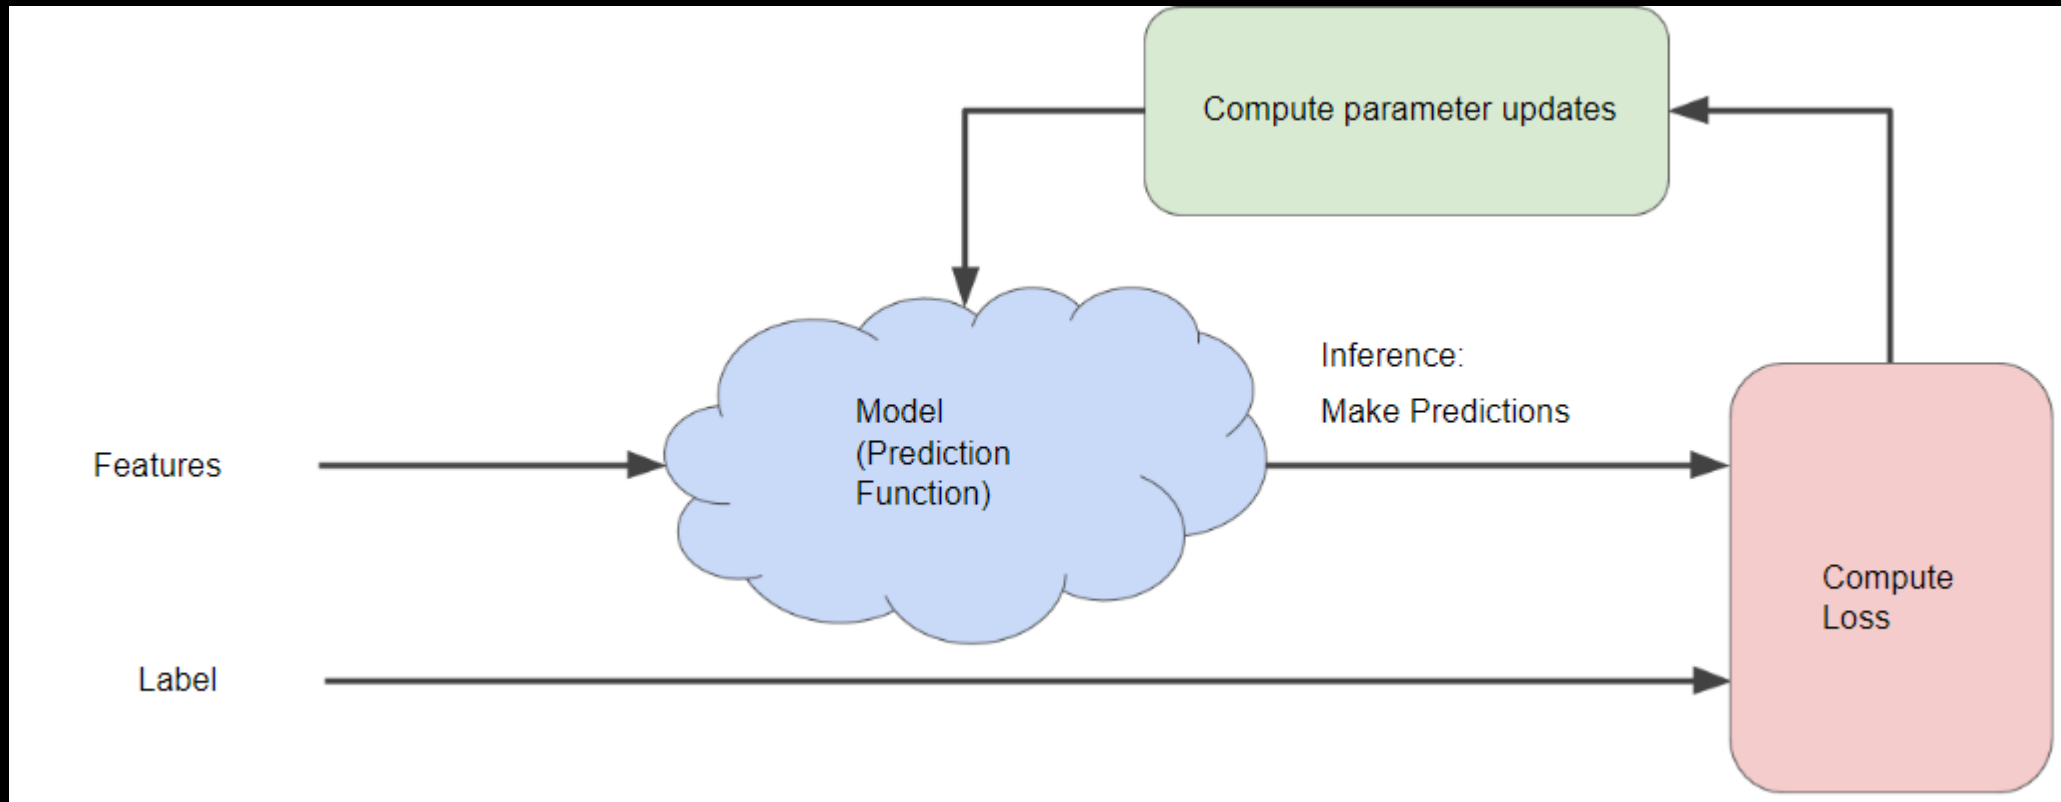

$$y(x, \mathbf{w}) = w_0 + w_1x + w_2x^2 \dots + w_Mx^M = \sum_{j=0}^M w_jx^j$$

- x is the input vector (features)
 - \mathbf{w} is the weights vector.
- The weights are the coefficient that are multiplied with the input vector (x) to produce an output (t).
 - So, the basic idea of **learning** is to **find the best set of weights that gives the most accurate results.**

Polynomial Curve Fitting

- To find the best set of weights, we have to minimize an error function.
- The process is as follows
 1. Get the dataset.
 2. Let the machine learn from the data (finding the weights).
 3. Compute the model's error – compare the output of the model (\hat{t}) with the true target value of the input (t).
 4. If the error is high, repeat the learning process.
 5. If the error is low, stop the learning process.

Polynomial Curve Fitting

Polynomial Curve Fitting

- To measure the error of the model, we use an error function called *sum of the squares*

$$E(\mathbf{w}) = \frac{1}{2} \sum_{n=1}^N \{y(x_n, \mathbf{w}) - t_n\}^2$$

Figure 1.3 The error function (1.2) corresponds to (one half of) the sum of the squares of the displacements (shown by the vertical green bars) of each data point from the function $y(x, \mathbf{w})$.

Polynomial Curve Fitting

- Interactive demo

<https://developers.google.com/machine-learning/crash-course/reducing-loss/playground-exercise>

Polynomial Curve Fitting

- The linear regression model is a polynomial function:

$$y(x, \mathbf{w}) = w_0 + w_1x + w_2x^2 \dots + w_Mx^M = \sum_{j=0}^M w_jx^j$$

- When building the model, we have to choose the order M of the polynomial
- Types of Polynomial functions: (<https://www.desmos.com/calculator>)

| Type | Form |
|-------------------------------|-------------------------------|
| Zero Polynomial Function | $P(x) = a = ax^0$ |
| Linear Polynomial Function | $P(x) = ax + b$ |
| Quadratic Polynomial Function | $P(x) = ax^2 + bx + c$ |
| Cubic Polynomial Function | $ax^3 + bx^2 + cx + d$ |
| Quartic Polynomial Function | $ax^4 + bx^3 + cx^2 + dx + e$ |

Polynomial Curve Fitting

- Four examples of the results of fitting polynomials having orders $M = 0, 1, 3,$ and 9 .
- Exercise: which is the best model that represent the data?

Polynomial Curve Fitting

- This a very complex model – *overfitting*.
 - The model only fits the training dataset; it will not recognize new samples.
 - If the model is given a new value (not part of the training set), it will give wrong output.
- We want to achieve a good **generalization**.
 - Generalization means that the model be accurate for unknown, new samples.

Polynomial Curve Fitting

- Using the RMSE error function to compute error of a model of degree M .

$$RMSE = \sqrt{\frac{\sum_{i=1}^N (prediction - true)^2}{N}}$$

Figure 1.5 Graphs of the root-mean-square error, defined by (1.3), evaluated on the training set and on an independent test set for various values of M .

[Go to Code](#)

Polynomial Curve Fitting

- To avoid overfitting, apply **regularization**.
- Regularization is a penalty term added to the error function to prevent coefficient from reaching large values.

- Error function with regularization

$$\tilde{E}(\mathbf{w}) = \frac{1}{2} \sum_{n=1}^N \{y(x_n, \mathbf{w}) - t_n\}^2 + \frac{\lambda}{2} \|\mathbf{w}\|^2$$

- λ is a parameter that controls the strength of the regularization
- $\|\mathbf{w}\|^2 = w_0^2 + w_1^2 + w_2^2 + \dots + w_m^2$

Polynomial Curve Fitting

Before regularization

After regularization

| Introduction |
| Polynomial Curve Fitting |
| Bayesian Probabilities |
| Bayesian Curve Fitting |

Bayesian Probabilities

- Bayes theorem is used to calculate the conditional probabilities.
 - Calculates the probability of the occurrence of an event given the occurrence of another event.
 - Example: what is the probability that the sky will rain *given that* there are clouds.
- Bayes' theorem is used to describe the uncertainty in model parameters, \mathbf{w} , after observing the dataset.

$$p(\mathbf{w}|D) = \frac{p(D|\mathbf{w})p(\mathbf{w})}{p(D)}$$

$$p(model|dataset) = \frac{p(dataset|model)p(model)}{p(dataset)}$$

Bayesian Probabilities

- Bayes theorem

$$p(\mathbf{w}|D) = \frac{p(D|\mathbf{w})p(\mathbf{w})}{p(D)} \quad \text{or} \quad p(\mathbf{w}|D) \propto p(D|\mathbf{w}) * p(\mathbf{w})$$

- $p(\mathbf{w})$, is the prior probability of the weights before observing data.
- $p(D, \mathbf{w})$, is the likelihood, expresses how probable the observed dataset is for different settings of the weights \mathbf{w} .
- $p(D)$, is the normalization constant, ensures that distribution integrates to one.
- $p(\mathbf{w}|D)$, is the posterior, represents what parameters are likely after observing the dataset.

| Bayesian Curve Fitting |

Bayesian Curve Fitting

- The dataset D is composed of feature values \mathbf{x} and target values \mathbf{t} . Thus, we can re-write the Bayesian formula as follows:

$$p(\mathbf{w}|\mathbf{x}, \mathbf{t}, \alpha, \beta) \propto p(\mathbf{t}|\mathbf{x}, \mathbf{w}, \beta)p(\mathbf{w}|\alpha)$$

Where:

- D is decomposed into \mathbf{x} (feature values) and \mathbf{t} (target values)
- β is a hyperparameter corresponds to the inverse of the variance.
- α is a hyperparameter controls the distribution of the model's parameters.
- The hyperparameters α and β can be used to determine a value for the regularization term λ by $\lambda = \frac{\alpha}{\beta}$.

Bayesian Curve Fitting

Figure 1.17 The predictive distribution resulting from a Bayesian treatment of polynomial curve fitting using an $M = 9$ polynomial, with the fixed parameters $\alpha = 5 \times 10^{-3}$ and $\beta = 11.1$ (corresponding to the known noise variance), in which the red curve denotes the mean of the predictive distribution and the red region corresponds to ± 1 standard deviation around the mean.
